

We should get rid of cars sooner or later, or cars will get rid of us, no matter what engines they use. It's just that simple. There are close to one billion cars in the world and close to 100 million cars manufactured each year. That's just a big waste of resources that are limited and can be used more wisely.

Is there a possible replacement for cars? Could there be a solution which gives us all the freedom and privacy that we are used to having in cars?

My favorite idea for future transport is to have no cars, just transport vehicles on demand, driven and directed by facilities in the ground below roads. The traveler would order a vehicle, set a starting point and destination, and when the vehicle shows up, they would use it and then leave it for somebody else to use. This vehicle should also be transported through the shafts in deep transport tunnels to travel to distant locations with higher speeds. Everything should be run by a system that is able to provide the quickest possible means of travel.

There is not a clear path in the future regarding transport, so the idea above is only one of many possible solutions. At the moment, the mainstream idea is electric cars. But this is just a selling trick, if you get electricity by using coal. It's just the wrong way to go. The solution is to rapidly decrease the number of cars and organize transport differently.
